

How to select the correct size DS6 soft starter for standard duty applications

Application

The DS6 is a two phase control soft starter utilized to accomplish motor starting using the reduced voltage method. Typically, the motor horsepower or kW rating is used to determine the required size of the soft starter. This document addresses other factors that require consideration in accomplishing the proper match of soft starter to the load.

Overview

Soft starter sizing is typically determined by the horsepower or kW rating of the motor, coupled with the mains operating voltage. Using this information, a table or graph is consulted to determine the minimum size of the soft starter for the application. If the application is considered to be severe duty, it is commonplace to select the next size larger soft starter to accommodate the higher load currents.

The initial graphs and tables published for the DS6 are based on an inrush value of 300% FLA of the motor. If the actual inrush current approaches a value of 400% FLA, the maximum allowable ramp times are significantly affected. Additionally, the ramp times also must be considered independently, as when the ramp times are increased even though the inrush current does not change, the maximum allowable current capacity is reduced. When selecting the size of the DS6 soft starter, Tables 1–4 may be used if the anticipated ramp times are 10 seconds or less. Please note that either 300% or 400% current limit refers to the maximum anticipated start current in terms of motor FLA (3x or 4x). The DS6 does not have a current limiter function. If the ramp times are expected to be longer, Tables 5–12 should be reviewed to ensure that the soft starter is not subjected to excessive current resulting in SCR failure. The size of the soft starter may be required to be increased specifically due to a longer ramp time.

Note: The DS6 soft starter may be incorrectly sized if based solely on motor horsepower or kW rating and mains voltage alone.

The DS6 soft starter requires that specific attention is given to two factors:

Ultimate load—the maximum inrush current that the soft starter will transmit anytime during the start process.

Ramp time—the expected, or required, ramp time required for the motor to achieve synchronous speed.

Example 1—30 hp motor (40A FLA) @ 460V application, maximum current 300% FLA with an estimated start ramp time of 8 seconds, 4 starts per hour. Consulting Table 1, the DS6-34DSX041NO-N soft starter shows an acceptable maximum motor size of 30 hp. Consulting Table 5, the maximum allowable start current is listed as 121A. Under these conditions, a DS6-34DSX041NO-N soft starter is the appropriate selection for this application.

Example 2—With the same operating conditions as in Example 1, it is determined that the ramp time must be extended to 12 seconds for the motor to achieve synchronous speed. Consulting Table 5, the maximum allowable start current @ 12 seconds is listed as 104A, less than the required 120A. Table 6 for the next higher size soft starter lists the maximum allowable start current @ 12 seconds as 140A. Under these conditions, the DS6-34DSX041NO-N soft starter would not be an appropriate selection. The next size higher soft starter, DS6-34DSX055NO-N, is the suitable choice, as the maximum allowable start current for these conditions is sufficient for proper operation.

Example 3—With the same operating conditions as in Example 1, it is determined that the inrush current requires a 400% current limit. This operating condition will also require a larger capacity soft starter (DS6-DSX055NO-N) to accommodate the higher operating current during the start ramp.
